

Communication Method	Description	Advantages	Disadvantages
<b>Wired Communication</b>	The robot is physically connected to a hand held controller or a computer through a cable.	<ul style="list-style-type: none"> <li>• Bidirectional communication</li> <li>• Consistent communication</li> <li>• Can provide power along with communication link and a tether in case of breakdown</li> </ul>	<ul style="list-style-type: none"> <li>• Creates constraint on movement around corners</li> <li>• Limits range to the length of available cable</li> <li>• Function is similar to that of the current pigging solution</li> </ul>
<b>Acoustic Communication</b>	Tracking via the acoustic wave generated by the friction between the robot and pipe wall.	<ul style="list-style-type: none"> <li>• Provides tracking capability without requiring a transmitter which is expensive and requires power supply</li> </ul>	<ul style="list-style-type: none"> <li>• Acoustic signals generated are cluttered by noise from vehicles and machinery above ground</li> <li>• No tracking data when stationary</li> <li>• Not capable of transmitting more complex data</li> </ul>
<b>Extremely Low Frequency (ELF)</b>	Communication through the use of Extremely Low Frequency (ELF) waves which are characterised as being in the range of 3-30 Hz	<ul style="list-style-type: none"> <li>• Bidirectional communication</li> <li>• Small and lightweight transmitters</li> <li>• Experiences low noise interference</li> </ul>	<ul style="list-style-type: none"> <li>• Experiences large attenuation and requires complex software to recover signal</li> </ul>
<b>Magnetic Communication</b>	Equip the robot with static magnetic field and detect it with a magnetometer	<ul style="list-style-type: none"> <li>• Low attenuation when used at low frequencies</li> <li>• Transmitters are very cheap</li> </ul>	<ul style="list-style-type: none"> <li>• Unidirectional communication</li> <li>• Bulky permanent magnets required to be put on robot in order to create static magnetic field</li> </ul>
