

| Communication method | Description | Advantages | Disadvantages |
|-----------------------|---|---|---|
| Wired communication | The robot is physically connected to a hand held controller or a computer through a cable. | <ul style="list-style-type: none"> - Bidirectional communication - Consistent communication - Can provide power along with communication link | <ul style="list-style-type: none"> - Creates a large constraint on movement around corners and up bends - Limits range to the length of available cable - Function is similar to that of the current pigging solution |
| Acoustic wave | Tracking via the acoustic wave generated by the friction between the robot and pipe wall. | <ul style="list-style-type: none"> - Provides tracking capability without requiring a transmitter | <ul style="list-style-type: none"> - Acoustic signals generated are cluttered by noise from vehicles and machinery above ground - Unidirectional communication from the robot to receiver above ground - Not capable of transmitting more complex data |
| ELF wave | Communication through the use of Extremely Low Frequency (ELF) waves which are characterised as being in the range of 3-30 Hz | <ul style="list-style-type: none"> - Bidirectional communication - Small and lightweight transceivers - Doesn't experience a lot of noise interference | <ul style="list-style-type: none"> - Experiences large attenuation and requires complex software to recover signal |
| Static Magnetic field | Equip the robot with static magnetic field and detect it with a magnetometer | <ul style="list-style-type: none"> - Low attenuation when used at low frequencies | <ul style="list-style-type: none"> - Unidirectional communication - Bulky permanent magnets required to be put on robot in order to create static magnetic field |
